Solar Education for NY SchoolPower ...Naturally

Solar Kit Lesson #2

Sunshine Timer

TEACHER INFORMATION

LEARNING OUTCOME
After collecting data on cloud cover using a simple instrument and displaying data through graphs, tables, and charts, students interpret data for patterns of cloud cover that affect solar-powered energy production and predict energy production under given cloud conditions.

LESSON OVERVIEW
Students use a simple and easy-to-understand homemade technological device, the sunshine timer, to monitor cloud cover over an extended study period. They become habituated to observing conditions in the sky such as location of the Sun and types of clouds present. This study provides daily and weekly opportunities for students to collect and display data; use graphs, tables, and charts to interpret data; make predictions; and relate patterns of cloud cover to their effect on solar energy production.

GRADE-LEVEL APPROPRIATENESS
This Level I/II Physical Setting lesson is intended for use in grades 3–6. It can easily be adapted for grades 7 and 8.

MATERIALS
- Student handouts
- 1 V, 400 mA mini–solar panel*
- Analog DC-powered clock (must run on one AA battery)
- Maximum temperature thermometer
- Highlighter (optional)

* Available in the provided Solar Education Kit; other materials are to be supplied by the teacher

SAFETY
Tell students not to look directly at the Sun. Permanent eye damage can result.

TEACHING THE LESSON
This lesson could easily be adapted to encompass fractions and percentages. It could readily be transferred to computer data-management software such as spreadsheets.

Preparation—Set up the sunshine timer: Remove the AA battery from the DC-powered clock. Use alligator clips to connect the mini–solar panel's red lead to the clock's positive (+)

battery terminal and black lead to the negative (-). The clock will run when the mini–solar panel is aimed at the Sun unless a cloud obscures the Sun. Set the clock to noon at the start of a data collection period. The clock will advance as long as clouds do not cover the Sun. In this way, the clock will record the number of hours of unobscured sunlight. Students can subtract the number of hours the clock advances from the number of hours of data collection to get the number of hours of cloud cover.

The clock can be powered by a mini–solar panel that is aimed within 45 degrees of facing the Sun directly. From August through April the Sun is within 45 degrees east of south to 45 degrees west of south for a three-hour period centered on noon. From May through July you will need to shorten the daily data collection period to two hours because the Sun will be at too great an angle from due south during the three-hour period centered on noon. Alternatively, you can extend the daily data collection period by adjusting the direction of the sunshine timer to track the Sun.

Opening Discussion: Begin by discussing how solar electric systems depend on radiation from the Sun to produce power. Demonstrate a mini–solar panel powering a small motor. Mention that the School Power Naturally project has installed solar electric systems in 50 New York State schools to partially address their energy needs. Explain that solar electricity is a growing energy source throughout New York State. Use information from the Background Information section to introduce the idea of peak electrical demand and the fact that the highest demand for electricity occurs during hot summer days when there are large amounts of sunshine.

Ask students what might hinder our using sunshine for electricity. What might New York State decision makers want scientists to study to determine if solar electric panels are a good way to supply electricity in the middle of the day?

Tell the students that they will conduct a long-term study of middle-of-the-day cloud cover. Demonstrate how the sunshine timer works and give students an opportunity to handle the timer and become familiar with it.

Help students determine where in the school or in the classroom they can place the cloud meter. It must receive sunlight for one to three hours around noontime unobscured by the shadows of trees, buildings, or other objects. It must face due south and tilt up at an angle to face the Sun at around noon. It must be protected from the weather.

Data Collection: Distribute the student handouts and explain the daily cloud logs. Have students record the length of the data collection period for each day and convert the time to minutes. At set intervals during the daily data collection period, have students check off the box that best fits the current cloud conditions. Have students use the "Weather Notes" section to record daily peak temperature. They could also use it for additional work involving cloud identification or to record experiences for other weather observation opportunities that you may want them to have.

Prediction: At or before the end of the data collection period, but before students check the sunshine timer, have them make a prediction on how many minutes of sunshine will have been recorded.

Data Collection: Have students record the length of sunshine for each day and convert it to minutes.

Data Calculation: Have students subtract the number of minutes of sunshine from the number of minutes for the data collection period to get the number of minutes of cloud cover. Students who would benefit from additional work with fractions or percentages might use these numbers for daily practice and to form additional weekly graphs.

Graphing: Distribute and explain graphs 1–3. Help students label the *x*- and *y*-axes. In the title of graph 2, students must fill in the number of minutes of the daily data collection. Have students fill in these graphs on a regular basis—for instance, daily or once a week.

Graph 1: This graph is actually five bar graphs on top of one another. Students should use a different color for each weather condition. For each day, have students record the number of times each weather condition is observed.

Graph 2: Have students graph their predictions with a pencil dot and the measured value as a bar colored with a highlighter.

Graph 3: Have students graph the peak daily temperature as a line graph.

Review Questions: Go over appropriate review questions daily, weekly, or at the end of the data collection period.

Have your predictions on the amount of sunshine improved over time? Have students discuss why.

What types of clouds or cloud cover seem to affect solar energy production the most?

What types affect it the least?

Visit schoolpowernaturally.org online to compare your data with the data available from the 50 New York schools having solar electric systems.

How do the solar intensity readings collected by the School Power Naturally schools compare to your daily sunshine readings? Have students discuss why these may be the same or different. Have them consider the length of time of daily data collection and the location of the schools.

How could solar electric power help provide electricity for the high midday demand of high-temperature days?

ACCEPTABLE RESPONSES FOR DEVELOP YOUR UNDERSTANDING SECTION

The results will vary depending on the kind and extent of cloud cover during the data collection period.

ADDITIONAL SUPPORT FOR TEACHERS

SOURCE FOR THIS ADAPTED ACTIVITY

The idea of using a solar-powered clock as a sunshine timer came from *Science Projects in Renewable Energy and Energy Efficiency*, written and designed by the National Renewable Energy Laboratory and published by the American Solar Energy Society, 1991.

The organization of classroom activities was adapted from *Renewable Energy Activities for Earth Science* prepared for the U.S. Department of Energy by the Solar Energy Project in cooperation with the New York State Education Department and the University at Albany Atmospheric Sciences Research Center (out of print).

BACKGROUND INFORMATION

Daily peak needs for electrical power in New York State's large metropolitan areas are closely coincident with available sunlight. New York's highest power demands occur during summer heat waves, when there are large amounts of sunshine.

Studies conducted by the University at Albany Atmospheric Sciences Research Center show that for the mid-Atlantic region (including downstate New York) sunlight is available when it is needed to offset peak power 60% to 70% of the time. This is comparable to much of Arizona, Florida, and California—the "traditional" solar areas.

The result is that, together with very small amounts of backup power (such as batteries) and/or programs to reduce peak demand for electricity, solar electric panels could provide a 100% guaranteed peak power source for New York's metropolitan areas.
